Measuring confidence in clinical decisions: the ambiguity effect in medical diagnosis. The statistical notion of the ambiguity effect in medical diagnosis was applied to measure the confidence of a clinician in a medical decision. The strategy used in the measurement of confidence is to equate the certainty in the decision of a physician with the uncertainty surrounding the patient's recovery in a scenario of "no treatment." When a patient is discharged with or without a recommended treatment, the doctor's assessment is regarded as being based on an act of observation. In this situation, the decision rule is described by the binormal distribution. The decision of a doctor is regarded as being a random variable that can be represented by an interval of probability. When the doctor's observation is affected by an "uncertainty variable" h (e.g., the complication probability in a condition with the possibility of a successful treatment) the observation is described by the beta distribution. In the decision rule, the expected value of h plays the role of a threshold value. Uncertainty in the decision is then estimated as a function of h and is evaluated by the degree of the shift in the corresponding belief functions. In this manner, one can measure the degree of uncertainty in the medical decision.

Diabetes mellitus and oral cancer: an American cancer society survey. The relationship between diabetes mellitus and oral cancer was analyzed in a population-based cancer registry of 438,789 individuals, approximately 1.6 million individuals older than 30 years. The association between oral cancer and

diabetes was determined through chi2 analysis. The odds ratios and relative risk ratios of developing oral cancer were assessed by age, sex, race, and the number of diagnosed diabetes mellitus. Those with diabetes mellitus were significantly more likely to develop oral cancer. The relative risk of developing oral cancer increased with the presence of diabetes mellitus for all age groups. However, the highest risk was observed in those younger than 60 years. The odds ratio for those with diabetes mellitus who had ever smoked was 3.08 (95% confidence interval 2.49-3.80), which was significantly higher than that for those who never smoked (odds ratio 2.02, 95% confidence interval 1.62-2.52).The
