The purpose of this study is to obtain a quantitative characterization of enzyme systems involved in the metabolism of arachidonic acid and other fatty acids and to relate these systems to the lipoxygenase and cyclooxygenase pathways. Specific attention will be given to the following: 1) studies of the microsomal fatty acid-peroxidase system; 2) effects of long-chain fatty acids on prostaglandin and leukotriene biosynthesis; 3) the metabolism of prostaglandin endoperoxide H₂. The techniques which will be used include high pressure liquid chromatography (HPLC), gas chromatography, thin layer chromatography, enzymatic methods and spectrophotometric techniques. The specific questions to be asked are: (1) How is arachidonic acid metabolized in eicosanoid biosynthesis? (2) Is there a direct relationship between arachidonic acid metabolism and the cyclooxygenase pathway? (3) Is there an obligatory relationship between the metabolism of linoleic acid and that of arachidonic acid? (4) What are the physiologic implications of our finding of a long-chain fatty acid esterase in the microsomal fraction of cells? Why is it that the world's best film festival, the Sundance Film Festival, always seems to find time to give the world a look at the new breakout comedy star of the year? This year, it's Kevin Hart, the funny man best known as an actor in the Straight Outta Compton movie franchise. Hart's big moment at Sundance, however, isn't about a movie but about a pair of pants. He is, in fact, the first and only black actor to host the closing night of the festival. Kevin Hart knows a thing or two about having a breakout moment, and he's about to turn that into the

The polycystic ovary syndrome (PCOS) is the most common endocrine disease in reproductive age women. Its pathophysiology is still far from clear. The incidence of PCOS is growing fast as a result of the increasing prevalence of obesity in reproductive age women. The aim of this study was to evaluate the dietary pattern of the women with PCOS. For three months, a PCOS family was followed in a dietary research facility. A semi-quantitative food frequency questionnaire and a 24 h-dietary recall were used. A total of 5 patients were involved in the study and the healthy women in the family were their controls. In a paired design, we compared the dietary data of patients with those of their own healthy relatives. The total intake of vegetables was low in the patients and their healthy relatives, the differences being highly significant. The intake of vegetable oils, bread, pasta, rye bread, pasta and cereal was high, the difference being significant. The differences between patients and their healthy relatives were also significant for fresh fruit, bread, pasta, rye bread, pasta and cereal. The differences were not significant for other vegetables, potatoes and potatoes products. The total energy intake was higher in the healthy relatives, but the difference was significant only for cereals and rye bread. The total dietary intake of vegetables and fruit was low in the women with PCOS and in their healthy female relatives. This is possibly related to the overweight and obesity of the women with PCOS. A more vegetable rich diet could contribute to the treatment of PCOS.
