An evolutionary analysis of the mean and variance of phenotypes associated with two alleles was carried out with a quantitative trait locus that was fixed during an experimentally induced initial mutation rate. Females were associated with one of two alleles, and males with the other allele. The effect of the two alleles on male and female phenotypes was analysed using a standard two-locus analysis. The theory of two loci was extended to include fitness effects on the mean and variance of male and female phenotypes, and the effects of maternal genotype on these fitness components were analysed. Only two of five new parameters showed significant effects in the actual experiment, and only one of five showed significant variance-covariance components. Fitness increases or decreases of up to 20% were observed, but the variance-covariance components were
