It must be used whenever new data is to be stored in the table. The statement is used to add data to a table, without disturbing the current data in the table. You can use the INSERT INTO statement to add new records to an existing table (called the target table), or to add records to a new table (called the source table). Because we are going to add new records to the customer table, it will be used as the target table. The table will have a row number or identity column for each new row and will have a column called customerID, with a value of 1 for the first row in the table, 2 for the second row, and so on. The statement creates a new row with the value of the column. The table will also have a column called userID, which is a column that contains the value of the userID you input. The INSERT statement keeps track of the row number of the new row. If you try to add the same row value more than once, it will overwrite the row and assign the next row number. The INTO clause tells the statement how to access the row or values being added. If you use the INTO clause, then the values are inserted into the columns of the table. If you do not use the INTO clause, then the values are added to a blank row in the table. The row or values are inserted in the columns from right to left.The average American commutes nearly 50 miles per day and spends approximately 35
